

Beryn Staub-Waldenberg

My program compiles and runs. I was finally able to fix a bug that I had with my split adjustments. Turns out I had the the query for the adjustments in ascending instead of descending order. The program seems to take about 30 seconds to run. There might be a few ways I could make the program more efficient for example I have a few different queries which retrieve similar (perhaps overlapping) data. So, some steps likely could've been further combined. It might be possible to retrieve all the intervals for a given ticker with one pass through of the days instead of searching through many days for each interval. I think I spent about 30 hours on this assignment.

Expected Score:

Correct output: 50/50

program obeys constraints: 3/3

write up complete: 3/3

less than 2 minutes: 1.5/1.5

filename format correct: .5/.5
